Keywords:
Gonadotropin-releasing hormone
Ovarian hyperstimulation syndrome
Pregnancy rate

ABSTRACT

Objective: To make a review of studies that assessed the outcomes of GnRH agonist oocyte triggering in comparison with hCG in prevention of ovarian hyperstimulation syndrome and pregnancy rates.

Methods: A systematic review of studies presented in the following database: PUBMED, Lilacs and Scielo submitted from January 2005 to October 2015. The keywords were ovulation induction, ovarian hyperstimulation syndrome and gonadotropin releasing hormone.

Results: One hundred fifty-four articles were found. From these, twelve studies were completely analyzed. Eight fulfilled the inclusion criteria and one was included after the bibliographic review of the previous ones. From these nine submitted articles, two are retrospective and the others are prospective.

Conclusion: The use of GnRH agonist for oocyte triggering was comparable with hCG and showed low frequency of ovarian hyperstimulation syndrome.

Resultados da maturação ocitótica final com agonistas do GnRH nos ciclos de reprodução assistida: uma revisão sistemática

RESUMO

Objetivo: Fazer uma revisão dos estudos que avaliaram os desfechos do agonista de GnRH no ovócito em comparação com hCG na prevenção da síndrome de hiperstimulação ovariana e nas taxas de gestação.

Métodos: Revisão sistemática de estudos presentes nos seguintes bancos de dados: Pubmed, Lilacs e Scielo, apresentados de janeiro de 2005 até outubro de 2015. As palavras-chave foram indução da ovulação, síndrome de hiperstimulação ovariana e hormônio liberador de gonadotropina.

Introduction

The gonadotropin releasing hormone (GnRH) agonist has been used for triggering final oocyte maturation in vitro fertilization (IVF) for a few years. The first authors to document this practice were Gonan and Casper, in 1990, obtaining in their study with eighteen patients, oocyte quality and quantity outcomes similar to hCG triggering. However, it was only with the rise of GnRH antagonist protocol that its use was truly propagated in the beginning of this century.2,3

The prevention of ovarian hyperstimulation syndrome (OHSS), fearsome iatrogenic complication of human reproduction techniques, became the main indication of this type of triggering. Several studies showed incidence’s reduction, mostly because of the early induction and short duration of LH surge.1–6

The aim of this study is to review the GnRH agonist triggering outcomes in comparison with hCG in the prevention of ovarian hyperstimulation syndrome and in pregnancy rates.

Materials and methods

The keywords used for the construction of this article were: ovulation induction, ovarian hyperstimulation syndrome and gonadotropin releasing hormone. The following database: Pubmed, Lilacs and Scielo were analyzed. The articles published from January of 2005 to October of 2015 in Portuguese, Spanish and English were selected by two researchers independently. If disagreement a third researcher was consulted. The inclusion and exclusion criteria were based on the main systematic reviews about the subject available. The inclusion criteria were: studies using GnRH agonist (GnRHa) for triggering that described its outcomes in pregnancy rates and/or OHSS, women with age between 18 and 40 years, BMI between 18 and 35 kg/m², non-smokers and with ovarian reserve of 3 or more antral follicles. It was excluded from this review, women that had any uterine pathology or malformation.

One hundred and fifty four published articles were found considering the keywords and filters used in association. After their abstracts reading, twelve articles were selected for posterior full read. From these, nine fit the inclusion criteria. The method was described in the form of a fluogram represented in Fig. 1. As a systematic review, approval of the local Research Ethics Committee wasn’t necessary.

Results

The articles data were summed up in Table 1 for comparative analysis. From 9 selected studies, seven were prospective including randomized clinical trials and cohorts. The oldest paper is from 2005 by Kolibianakis et al. fulfilled in two human reproduction centers, one in Belgium and the other in Germany whilst the most recent is from 2014, by Declerq et al. The highest population assayed was in Spain with 1171 women and the smallest in Cyprus with only 44 patients.

Discussion

The GnRH agonist use for triggering oocyte final maturation was propagated as prevention to ovarian hyperstimulation syndrome for its effect in LH surge. It has shorter half-life than hCG stimulation and decreases the vascular endothelial factor growth (VEFG1) production which is the main developer of the syndrome.7

Kolibianakis et al.,8 in his randomized clinical trial, with 106 women in two European centers found in one of them statistic significant decrease (p = 0.012) in pregnancy rate in the agonist use group (5.6% vs 41.7%) and a clear reduction, though not statistic significant, in the same group in the second center (2.9% vs 16.7%). Higher implantation rate was also described in the hCG group and no OHSS case was observed in neither one. Thus, no advantaged of the agonist was noted in the study.

However, the others screened studies demonstrated better results. Melo et al.9 made a prospective randomized cohort with 100 oocyte donors. No OHSS was found in the agonist group vs 16% in hCG group whilst the implantation, pregnancy and miscarriage rates were similar in both groups. Bodri et al.,10 in the same year, observed resembling results in his retrospective study with higher population (n = 1171). Thirteen cases of OHSS (2.08%) in the hCG group and none in the agonist one was found and comparable outcomes between the groups as clinical pregnancy rates: 42.4% vs 38.8% and implantation rate: 29.1% vs 25.9%.

Simanoglu et al.,11 in a prospective study with oocyte donors, also found absence of the syndrome in the agonist group against 4 cases in the hCG one.

The association of final oocyte maturation with GnRH agonist and posterior freezing of oocyte and embryos (freeze-all strategy) is another method. Devroey12 proposed the possibility of an OHSS free-clinic with this approach in an opinion article. Griesinger et al.13 used this strategy to evaluate...

Period: 2005 to 2015

Database: PUBMED, Lilacs e Scielo
154 articles were found with posterior abstract reading.

Keywords:
- Induction ovulation;
- Ovarian hyperstimulation syndrome;
- Gonadotropin releasing hormone

Inclusion criteria:
• Triggering with GnRH agonist;
• Outcomes described in the study;
• Ovarian reserve of 3 or more antral follicles;
• BMI: 18-35Kg/m²;
• 18 to 40 years-old;
• Non-smokers;

12 articles screened to full-text reading

Inclusion criteria:

GnRHa, gonadotropin releasing hormone antagonis; hCG, human chorionic gonadotropin; OHSS, ovarian hyperstimulation syndrome.

a Study non-comparative with hCG.
b Studies show a comparison between hCG with GnRH agonist and isolated hCG.
The use of GnRH agonist for oocyte final maturation was comparable with hCG and some studies didn’t demonstrate statistical differences in implantation and pregnancy rates. Few studies that associate hCG with GnRH didn’t demonstrate statistical differences in the rates aforementioned. The efficacy in decrease ovarian hyperstimulation syndrome also is clear when not associated with hCG. The association with freeze-all strategy promotes even higher reduction of the syndrome. However, its complete elimination remains a challenge.
